Case Predictive Maintenance: Paper CO

The following is a fictional case study designed to loosely resemble the work you might undertake on a project. It will test your ability to handle big data and perform statistical/machine learning analyses as well as your ability to communicate your findings and derive commercial insight from your technical work. You may perform the analyses using any computational language you wish (including at least one tool different from excel). ***Please submit your code along with your presentation and the requested results file by the date agreed with the recruiting team****.*

Scenario:

Paper CO is an important player that produces mainly cellulose providing this important material for the paper makers and for their paper machines. The market is becoming more and more challenging due to international prices downfall of cellulose, see Figure 1.

Due to the challenging scenario, Paper Co is starting a project to reduce costs in maintenance avoiding over maintain some specific assets, and keeping the same availability of all the processes. To perform that, it will be necessary to predict failures in the selected assets.

The head of operations has asked whether it is possible to predict such events and based on your answers he will change the maintenance plans.

Your mission:

We have scheduled a meeting in one-week time with the head of operations in which you will present your findings and provide recommendations about changing the maintenance plans. As far as you know the maintenance plan is done with fixed frequency by calendar time.

The first phase is to check the viability of the remaining useful life (RUL) or/and a model to predict the failure with at least 20 cycles ahead.

For training your model you will receive a dataset with information of 100 events of failures on these assets. See **Table 1** for the information available. In the meeting is also necessary to demonstrate your understanding of the problem and show some statistics of the assets to illustrate the problem and the proposed solution.

Using the trained model, you should score for each asset id on the test data providing the information if the asset will fail after more than 20 cycles (probability 0-1) or (Vitor: "and") (preferably) how many cycles left the asset still has (RUL). You will submit the test file output which has to contain a single column and one line for each test sample (100) providing the information above.

Your prediction will be scored using quality KPIs for machine learning algorithms, be prepared to comment on the KPIs during the interview. You can simulate scenarios to demonstrate how the model performs against a naive process of changing the asset in a fixed period.

Finally, you will have to answer how the maintenance team will use your model to reduce costs.

Artifact 1: Training and test dataset

dataset_pred_maint.zip

Table 1: Dataset with information of failures for each asset id.

Field name	Description
Asset id	Asset code. The code represents a complete run of the asset until its failure. After its failure, it is replaced by another asset with id + 1 code. "The complete run has many operation cycles." (Vitor)
Runtime	A measure of time that resets after failure. "The last runtime - how many operation cycles the asset performed until fail." (Vitor)
Setting1	Setpoint 1
Setting2	Setpoint 2
Setting3	Setpoint 3
Tag1	Sensor 1
Tag2	Sensor 2
...	...
Tag21	Sensor 21
